Aims and Objectives:

To design a simplified yet robust linear control system for coordinating a drone swarm capable of executing complex tasks (e.g., dynamic formations) using off-the-shelf hardware and decentralized algorithms.

1. Swarm Control Basics:

- Stabilize individual drones using PID controllers for altitude, and position.
- Implement algorithms for decentralized swarm coordination (velocity alignment, formation keeping).

2. Task Execution:

- Demonstrate dynamic formation changes (e.g., line \rightarrow circle \rightarrow diamond).
- Enable collision-free navigation in obstacle-dense environments using repulsion-based control.

3. Intercommunication:

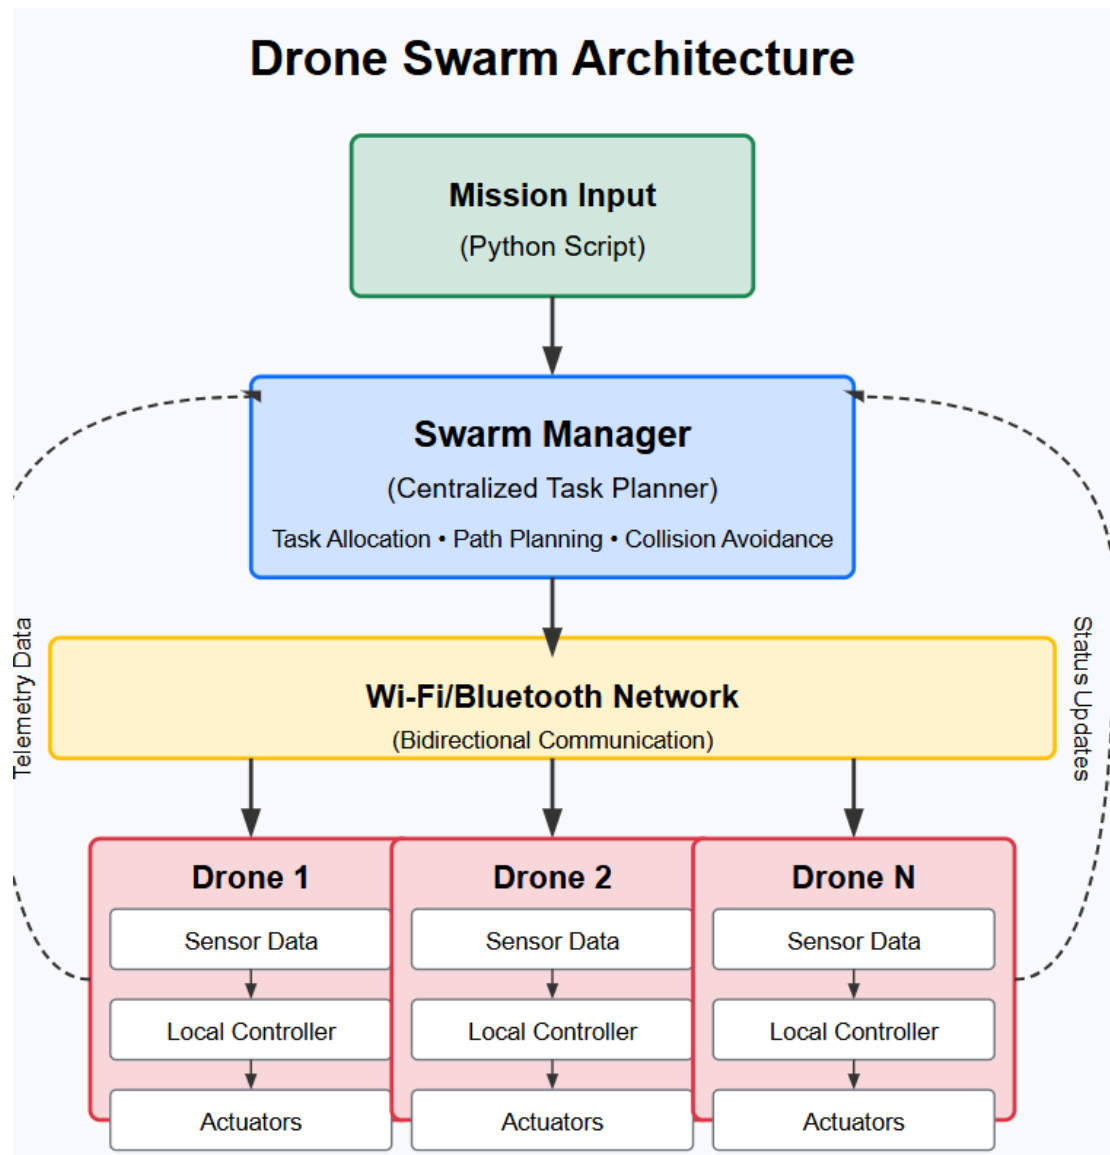

- Use Wi-Fi/Bluetooth for peer-to-peer communication (using ESP32).
- Implement lightweight messaging for position/velocity sharing (e.g., UDP packets).

4. Validation:

- Testing in simulation (Gazebo) and with a hardware 3-drone setup.

Block Diagram:

Key Components:

1. Drones:

- o Use pre-built drones (e.g., Crazyflie 2.1) with built-in STM32 controllers and radios.
- o Sensors: IMU (gyro/accelerometer), optical flow for indoor positioning.

2. Communication:

- o Wi-Fi Broadcast: Each drone broadcasts its state (x, y, z, velocity) over UDP.

National University of Sciences and Technology (NUST) School of Electrical Engineering and Computer Science

- o Python-based Swarm Manager: Runs on a laptop to assign tasks and monitor swarm status.

3. Control Algorithms:

- o PID for Individual Stability:
 - ☐ Altitude control via throttle adjustment.
 - ☐ Attitude control (pitch/roll) using gyro feedback.
- o Swarm-Level Coordination:
 - ☐ Velocity Consensus: Adjust drone velocity to match neighbors' average.
 - ☐ Formation Control: Offset tracking

Real-World Setup

1. Hardware:

Drones: 3.

Communication: Built-in Crazyradio PA (2.4 GHz) for low-latency control.

Positioning:

Outdoor: GPS module.

2. Software:

- Firmware: Extend Crazyflie's PID controller for swarm logic.
- Swarm Manager: Python script using cflib library to send setpoints.

Expected Results:

1. Basic Swarming:

- a. Drones maintain formation with $\pm 0.3\text{m}$ accuracy in moderate turbulence.
- b. Seamless velocity alignment within 2 seconds of disturbance.

2. Complex Tasks:

- a. Transition between 3 formations in < 30 seconds.
- b. Navigate obstacle courses with a good success rate.

3. Scalability:

- a. A system architecture design that supports up to 3 drones with $< 100\text{ms}$ communication latency.

Conclusion:

This project simplifies drone swarm control while retaining the ability to execute complex tasks. By leveraging affordable, off-the-shelf drones and lightweight algorithms, it demonstrates core principles of linear control systems in multi-agent coordination. The results will provide a foundation for future work on adaptive control or machine learning-enhanced swarming.
